**Background:** Validation ensures accurate reporting of health care-associated infections (HAIs). Ideal methods are being developed for validating surgical site infections (SSIs) reported to the National Healthcare Safety Network (NHSN). Oregon hospitals began mandatory public reporting of coronary artery bypass graft (CABG) SSIs in 2009. We assessed the validity of CABG SSI data reported by Oregon hospitals to inform strategies for optimal SSI validation.

**Methods:** We reviewed all SSIs reported to NHSN for CABG procedures during 2009–2010 from 14 Oregon hospitals required to report CABG SSI. We also selected 20 nonreported CABG procedures with the longest duration from each hospital for each year to identify procedures with a greater likelihood of unreported SSI. This sample was combined with the reported CABG SSIs and randomized for blinded review by the Oregon Health Authority (OHA). OHA determined SSI status using 2010 NHSN surveillance criteria. Discordant SSI determinations were adjudicated through follow-up discussions with hospital infection prevention staff. The adjudicated SSI determination served as the reference standard for sensitivity and specificity analyses.

> Results: OHA reviewed 703 CABG procedures; 133 (19%) were NHSNreported SSIs. Adjudication of 65 discordant cases identified 12 unreported CABG SSIs (false negatives). We identified a total of 140 SSIs (true positives). The sensitivity and specificity of hospital SSI reporting were 91% and 99%, respectively. The estimated positive predictive value among those reported to have an SSI was 96%. The estimated negative predictive value among those reported not to have an SSI was 98%. Among CABG SSIs agreed upon by hospitals and OHA, 30% had discordant levels of infection (superficial vs. deep vs. organ/ space). Reasons for discordance included interpretation of NHSN SSI definition and lack of post-discharge surveillance follow-up.

> > **Conclusions:** Validating reported SSI data improves accuracy of hospital-based SSI surveillance. Targeted selection of nonreported CABGs of longest duration is useful to select procedures at-risk for SSI. Discussing discordant findings improves the quality of validation and informs key elements of surveillance.

## Background

- Validation ensures accurate reporting of health careassociated infections (HAIs).
- Oregon hospitals began mandatory public reporting of surgical site infections (SSIs) associated with coronary artery bypass graft (CABG) surgeries in 2009 to the National Healthcare Safety Network (NHSN).
- » Two types of surgeries:
  - CBGB: CABG with both chest and donor site INCISIONS
  - CBGC: CABG with chest incision only
- SSIs, which account for 21.8% of acute health care HAIs, cause significant morbidity and mortality.
- Studies on SSI validation demonstrate a wide range of sensitivity values from 75% to 96.7% for reported data.

# **Objectives**

- Assess the validity of CABG SSI data reported by Oregon hospitals
- Inform strategies for optimal SSI validation

# Methods

- Population
  - » All 14 Oregon hospitals required to report CABG SSIs to NHSN from 2009–2010.
- Sample
  - We reviewed all NHSN reported CABG SSIs from procedures performed during 2009–2010 as well as a sample of procedures not reported as SSIs to NHSN.
  - For the sample of procedures not reported as associated with SSIs, we selected the 20 procedures with longest duration from each hospital for each year to identify procedures with greater likelihood of SSI.
  - SSI and nonSSI procedures were randomized for blinded review by the Oregon Health Authority (OHA) validation team.
- Protocol
  - » The OHA validation team determined SSI status using 2010 NHSN definitions.
- Analysis
  - Cases with discordant SSI determinations were adjudicated through follow-up discussions with hospital infection prevention
  - Sensitivity and specificity of CABG SSI reported were determined.

## Results

- OHA reviewed 693 medical records with 703 CABG procedure sites; 133 (19%) were NHSN-reported SSIs.
- Adjudication of 65 discordant cases identified 12 unreported CABG SSIs (false negatives).
- We identified a total of 140 SSIs (true positives).
- The sensitivity and specificity of hospital SSI reporting were 91% and 99%, respectively.
- The estimated positive predictive value among those reported to have an SSI was 96%.
- The estimated negative predictive value among those reported not to have an SSI was 98%.
- Among CABG SSIs agreed upon by hospitals and OHA, 32% had discordant levels of infection (superficial vs. deep vs. organ/space).
- 5 of 11 SSIs which changed infection type were missed because surveillance did not continue after initial detection of SSI.

### Pre-adjudication of procedures reviewed

**Table 4b** Post-adjudication of procedures reviewed

**Table 5** Summary table of reasons for missed or overcalled
 SSIs – Oregon, 2009–2010

**Table 6** Types of true surgical site infections reported by
 hospitals and OHA pre- and post-adjudication

n (post-adjudication)								
No infection	Superficial incisional	Deep incisional	Organ/Space	Total				
558	5	6	1	570				
4	71	1	2	78				
1	1	26	3	31				
0	0	2	22	24				
563	77	35	28	703				

### Conclusions

- Most SSIs reported to NHSN by hospitals were true infections.
- Reasons for underreporting in hospitals included lack of post discharge surveillance in the outpatient setting.
- Most reasons for overreporting were due to variations in case definition interpretation.
- No clear association was found between facility size, number of SSIs, and missed SSIs.
- Change in infection type (i.e., superficial vs. deep vs. organ/ space) was partly due to inadequate monitoring of infections following initial detection.
- Validating reported SSI data improves accuracy of hospitalbased SSI surveillance.

### Recommendations

- Ensure full data access for reviewers, including outpatient and readmission notes.
- Post discharge surveillance is an important aspect of SSI infection detection, which should include continued monitoring for changes following initial identification.
- Targeted selection of nonreported CABGs of longest duration is useful to select procedures at risk for SSI.
- Discussing discordant findings improves the quality of validation and informs key elements of surveillance.
- Adapt CDC's Validation Toolkit for SSIs following CBGB/CBGC procedures and pilot in facilities.
